NOVEL USES OF ANTIBODIES AGAINST ACHE AND PEPTIDES THEREOF

Novel uses of antibodies against AChE and peptides thereofField of the invention

The invention is directed to the field of diagnosis of a stressed condition of the central nervous system (CNS). Specifically, the invention relates to the evaluation the levels of acetylcholinesterase and fragments thereof, for determining said stressed CNS condition. The stressed CNS condition includes penetrance of high molecular weight substances through the blood-brain barrier, and stress due to psychological, chemical and physical insults.

Introduction

The enzyme Acetylcholinesterase (AChE) is expressed in brain tissue, but also in most hematopoietic cell lineages. AChE is expressed in many parts of the vertebrate embryo, with a developmentally regulated pattern in specific cell types and tissues during the embryonic and adult stages. AChE diversity is noted in several pathological states, such as Alzheimer's disease, where AChE activity was shown to decrease in the brain.

AChE pre-mRNA undergoes alternative splicing. The synaptic splice variant, AChE-S mRNA, is formed by splicing of exon 4 to exon 6. AChE-E mRNA is formed by splicing of exon 4 to exon 5. AChE-R mRNA is formed by lack of splicing of pseudointron 4, yielding the E1-E2-E3-E4-I4-E5 mRNA transcript.

It has now surprisingly been found that the C-terminal region of the AChE-R mRNA translation products occurs as a natural peptide.

It has further surprisingly been found that AChE-R mRNA, AChE-R protein, and the C-terminal peptide of AChE-R, are elevated in response to CNS insults. These insults include psychological, chemical, and physical insults. It has further been found that the blood-brain barrier is disrupted following stress insults, and that occurrence of said C-terminal peptide in fluids of the central nervous system may serve as an indicator of central nervous system stress and of disruption of the blood-brain barrier.

#### Summary of the invention

This invention relates to an antibody recognizing acetylcholinesterase or a C-terminal peptide derived from acetylcholinesterase, for use in diagnosing central nervous system (CNS) stress, elevated glucocorticoid level, or disruption of the blood-brain barrier. The CNS stress is preferably CNS stress caused by psychological, chemical, or physical insult. The antibody preferably recognizes a C-terminal peptide derived from Acetylcholinesterase. The C-terminal peptide is preferably SEQ ID no. 1, 2, or 3. Further preferably, the antibody is monoclonal.

The invention also provides a method for the diagnosis of central nervous system (CNS) stress, elevated glucocorticoid level, or disruption of the blood-brain barrier in a mammal, comprising obtaining a sample from said mammal, contacting said sample with an antibody of the invention,

removing unbound antibody, and detecting the extent of reaction between said antibody and acetylcholinesterase or a fragment thereof present in said sample. The said CNS stress is preferably CNS stress caused by physical, chemical, or psychological insult. In a preferred embodiment of the invention, the physical insult is head injury, head trauma, or exposure to irradiation. In a further preferred embodiment of the invention, the chemical insult is exposure to insecticide or nerve gas.

The sample is preferably a serum or cerebrospinal fluid sample.

#### Brief descriptions of the Figures

Fig. 1 shows detection of AChE in CSF by antibodies against the common domain of AChE (left), and by anti-ARP antibodies (right);

Fig. 2 shows detection of AChE in brain tissues of transgenic mice expressing human AChE constructs;

Fig. 3 shows that ARP accumulates in the serum under stress. Top: Ponceau-stained polyacrylamide gels, Bottom: detection of ARP and AChE (arrows) in the immunoblot by anti-ARP antibodies;

Fig. 4 shows Blood-Brain Barrier penetrance under stress;

Fig. 5 shows examples of CT scans of patients and statistical analysis of regions displaying enhanced signal therein.

#### Detailed description of the invention

A number of terms as used herein is defined hereinbelow

-AChE, Acetylcholinesterase;

- AS, antisense;
- AS-ODN, antisense oligodeoxynucleotide;
- ARP, acetylcholinesterase "readthrough" peptide;
- ASP, acetylcholinesterase "synaptic" peptide;
- BuChE, Butyrylcholinesterase;
- CNS, central nervous system;
- common domain, the region of AChE which is common to all splice variants, includes exons 1-4;
- CSF, cerebrospinal fluid;
- GST, glutathione-S-transferase;
- ODN, oligodeoxynucleotide;
- ORF, open reading frame;
- RT, room temperature;
- UTR, untranslated terminal region;
- WBC, white blood cells.

A number of methods of the art of molecular biology are not detailed herein, as they are well known to the person of skill in the art. Such methods include site-directed mutagenesis, PCR cloning, expression of cDNAs, analysis of recombinant proteins or peptides, transformation of bacterial and yeast cells, transfection of mammalian cells, and the like. Textbooks describing such methods are e.g., Sambrook *et al.*, Molecular Cloning A Laboratory Manual, Cold Spring Harbor Laboratory; ISBN: 0879693096, 1989, Current Protocols in Molecular Biology ,by F. M.

Ausubel, ISBN: 047150338X, John Wiley & Sons, Inc. 1988, and Short Protocols in Molecular Biology, by F. M. Ausubel *et al.* (eds.) 3rd ed. John Wiley & Sons; ISBN: 0471137812, 1995. These publications are incorporated herein in their entirety by reference. Furthermore, a number of immunological techniques are not in each instance described herein in detail, as they are well known to the person of skill in the art. See e.g., Current Protocols in Immunology, Coligan *et al.* (eds), John Wiley & Sons, Inc., New York, NY.

The invention comprises anti-AChE antibodies and the use thereof for the diagnosis of pathological conditions of the CNS. Polyclonal antibodies may be generated in rabbits, chicken, mice, rats, sheep, or similar mammals. For generation of antibodies against a peptide of the invention, the peptide is produced by recombinant DNA technology in mammalian cells, as described in the above general references for molecular biology. Alternatively, the peptide may be synthetically produced by organic chemistry. The peptide may also be produced in bacterial or insect cells as detailed in the above-noted Current Protocols in Molecular Biology, chapter 16.

The peptide is purified from the cells in which it has been produced. Peptide purification methods are known to the person of skill in the art and are detailed e.g., in the above-noted Current Protocols in Molecular Biology, chapter 16, and in Current Protocols in Protein Science, Wiley and Sons Inc. Chapters 5 and 6. Advantageously, the peptide may be produced as a fusion with a second protein, such as Glutathione-S-transferase or the

like, or a sequence tag, such as the histidine tag sequence. The use of fusion or tagged proteins simplifies the purification procedure, as detailed in the above-noted Current Protocols in Molecular Biology, chapter 16, and in the instructions for the his-tag protein expression and purification kit, as available from Qiagen GmbH, 40724 Hilden, Germany.

If the protein or peptide has been expressed as a fusion protein, it may be desirable to cleave the fusion partner before using the protein for the generation of antibodies, in order to avoid generation of antibodies against the fusion partner. The cleavage of fusion partners and the isolation of the desired protein is described in the above-noted Current Protocols in molecular Biology, chapter 16. Vectors, protocols and reagents for expressing and purifying maltose-binding protein fused recombinant proteins are also available commercially.

When producing a peptide of the invention, it may be desirable not to remove the fusion partner, as the fusion protein may stimulate the production of antibodies against the peptide. Generally, this consideration may be relevant when generating antibodies from peptides that are less than 50 amino acids in length. In particular, it has been found that the ARP peptide, when injected, is virtually non-immunogenic. A Keyhole Limpet hemocyanin (KLH)-conjugated ARP peptide was found to elicit antibodies unable to detect ARP or acetylcholinesterase. Antibodies capable of detecting ARP were successfully generated using a Glutathione-S-transferase-ARP fusion protein (detailed hereinbelow). Accordingly, in a preferred embodiment of the invention, antibodies are

elicited using a conjugate or fusion protein of the peptide of the invention as antigen. A preferred fusion partner is Glutathione-S-transferase.

As noted further above, the peptide may also be synthesized by chemical methods known in the art of chemistry.

The generation of polyclonal antibodies against proteins is described in chapter 2 of Current Protocols in Immunology, Wiley and Sons Inc. The generation of antibodies against peptides may necessitate some changes in protocol, because of the generally lower antigenicity of peptides when compared to proteins. The generation of polyclonal antibodies against peptides is described in the above-noted Current Protocols in Immunology, chapter 9, and exemplified hereinbelow.

Monoclonal antibodies may be prepared from B cells taken from the spleen or lymphnodes of immunized animals, in particular rats or mice, by fusion with immortalized B cells under conditions which favor the growth of hybrid cells. For fusion of murine B cells, the cell line Ag-8 is preferred.

The technique of generating monoclonal antibodies is described in many articles and textbooks, such as the above-noted chapter 2 of Current Protocols in Immunology. Chapter 9 therein describes the immunization, with peptides, of animals. Spleen or lymphnode cells of these animals may be used in the same way as spleen or lymphnode cells of protein-immunized animals, for the generation of monoclonal antibodies as described in chapter 2 therein.

The techniques used in generating monoclonal antibodies are further described in Kohler and Milstein, Nature 256, 495-497, 1975 and in USP 4,376,110.

In the preparation of antibodies from a gene bank of human antibodies the hypervariable regions thereof are replaced by almost random sequences, is described in USP 5,840,479. This method of antibody generation is preferred if it is difficult to immunize an animal with a given peptide or protein. The peptide of the invention may be poorly immunogenic, even as a conjugate. The antibodies described in USP 5,840,479 are further preferred if it is desired to use antibodies with a structure similar to human antibodies, for instance, when antibodies are desired that have low immunogenicity in humans.

Once a suitable antibody has been identified, it may be desired to change the properties thereof. For instance, a chimeric antibody may achieve higher yields in production. Chimeric antibodies wherein the constant regions are replaced with constant regions of human antibodies are further desired when it is desired that the antibody be of low immunogenicity in humans. The generation of chimeric antibodies is described in a number of publications, such as Cabilly *et al.*, Proc. Natl. Acad. Sci. USA 81, 3273, 1984, Morrison *et al.*, Proc. Natl. Acad. Sci. USA 81, 6851, 1984, Boulianne *et al.*, Nature 312, 643, 1984, EP 125023, EP 171496, EP 173494, EP 184187, WO 86/01533, WO 87/02671, and Harlow and Lane, Antibodies: A Laboratory Manual, Cold Spring harbor Laboratory, 1988.

The term "antibody" is also meant to include both intact molecules as well as fragments thereof, such as, for example, Fab and F(ab')<sub>2</sub>, which are capable of binding antigen. Fab and F(ab')<sub>2</sub> fragments lack the Fc fragment of intact antibody, clear more rapidly from the circulation, and may have less non-specific tissue binding than an intact antibody (Wahl *et al.*, J. Nucl. Med. 24, 316-325, 1983).

It will be appreciated that Fab and F(ab')<sub>2</sub> and other fragments of the antibodies useful in the present invention may be used for the detection and quantitation of the peptide of the invention and of intact AChE or its isoforms, according to the methods disclosed herein for intact antibody molecules. Such fragments are typically produced by proteolytic cleavage, using enzymes such as papain (to produce Fab fragments) or pepsin (to produce F(ab')<sub>2</sub> fragments).

An antibody is said to be "capable of binding" a molecule if it is capable of specifically reacting with the molecule to thereby bind the molecule to the antibody. The term "epitope" is meant to refer to that portion of any molecule capable of being bound by an antibody, that can also be recognized by that antibody. Epitopes or "antigenic determinants" usually consist of chemically active surface groupings of molecules such as amino acids or sugar side chains, and have specific three-dimensional structural characteristics as well as specific charge characteristics.

An "antigen" is a molecule or a portion of a molecule capable of being bound by an antibody, which is additionally capable of inducing an animal to produce antibody capable of binding to an epitope of that antigen. An

antigen may have one or more than one epitope. The specific reaction referred to above is meant to indicate that the antigen will react, in a highly selective manner, with its corresponding antibody and not with the multitude of other antibodies which may be evoked by other antigens.

The antibodies, including fragments of antibodies, useful in the present invention, may be used to quantitatively or qualitatively detect the peptide of the invention, in a sample. This can be accomplished by immunofluorescence techniques employing a fluorescently or color-labeled antibody (see below) coupled with light microscopic, flow cytometric, or fluorometric detection.

The antibodies (or fragments thereof) useful in the present invention may be employed histologically, as in immunofluorescence or immunoelectron microscopy, for *in situ* detection of a peptide of the invention. *In situ* detection may be accomplished by removing a histological specimen from a mammal, and providing the labeled antibody of the present invention to such a specimen. The antibody (or fragment) is preferably provided by applying or by overlaying the labeled antibody (or fragment) to a biological sample. Through the use of such a procedure, it is possible to determine not only the presence of the peptide, but also its distribution on the examined tissue. Using the present invention, those of ordinary skill will readily perceive that any of wide variety of histological methods (such as staining procedures) can be modified in order to achieve such *in situ* detection.

Such assays for the peptide of the invention typically comprise

incubating a biological sample, such as a biological fluid, a tissue extract, freshly harvested cells such as lymphocytes or leukocytes, or cells which have been incubated in tissue culture, in the presence of a labeled antibody capable of identifying the peptide, and detecting the antibody by any of a number of techniques well known in the art.

The biological sample may be treated with a solid phase support or carrier such as nitrocellulose, or other solid support or carrier which is capable of immobilizing cells, cell particles or soluble proteins. The support or carrier may then be washed with suitable buffers followed by treatment with a detectably labeled antibody in accordance with the present invention, as noted above. The solid phase support or carrier may then be washed with the buffer a second time to remove unbound antibody. The amount of bound label on said solid support or carrier may then be detected by conventional means.

By "solid phase support", "solid phase carrier", "solid support", "solid carrier", "support" or "carrier" is intended any support or carrier capable of binding antigen or antibodies. Well-known supports or carriers, include glass, polystyrene, polypropylene, polyethylene, dextran, nylon amyloses, natural and modified celluloses, polyacrylamides, and magnetite. The nature of the carrier can be either soluble to some extent or insoluble for the purposes of the present invention. The support material may have virtually any possible structural configuration so long as the coupled molecule is capable of binding to an antigen or antibody. Thus, the support or carrier configuration may be spherical, as in a bead, cylindrical, as in

the inside surface of a test tube, or the external surface of a rod. Alternatively, the surface may be flat such as a sheet, test strip, etc. Preferred supports or carriers include polystyrene beads. Those skilled in the art will know many other suitable carriers for binding antibody or antigen, or will be able to ascertain the same by use of routine experimentation.

The binding activity of a given lot of antibody, of the invention as noted above, may be determined according to well known methods. Those skilled in the art will be able to determine operative and optimal assay conditions for each determination by employing routine experimentation.

Other such steps as washing, stirring, shaking, filtering and the like may be added to the assays as is customary or necessary for the particular situation.

One of the ways in which an antibody in accordance with the present invention can be detectably labeled is by linking the same to an enzyme and used in an enzyme immunoassay (EIA). This enzyme, in turn, when later exposed to an appropriate substrate, will react with the substrate in such a manner as to produce a chemical moiety which can be detected, for example, by spectrophotometric, fluorometric or by visual means. Enzymes which can be used to detectably label the antibody include, but are not limited to, malate dehydrogenase, staphylococcal nuclease, delta-5-steroid isomerase, yeast alcohol dehydrogenase, alpha-glycerophosphate dehydrogenase, triose phosphate isomerase, horseradish peroxidase, alkaline phosphatase, asparaginase, glucose

oxidase, beta-galactosidase, ribonuclease, urease, catalase, glucose-6-phosphate dehydrogenase, glucoamylase and acetylcholin-esterase. The detection can be accomplished by colorimetric methods which employ a chromogenic substrate for the enzyme. Detection may also be accomplished by visual comparison of the extent of enzymatic reaction of a substrate in comparison with similarly prepared standards.

Detection may be accomplished using any of a variety of other immunoassays. For example, by radioactive labeling the antibodies or antibody fragments, it is possible to detect receptor tyrosine phosphatase (R-PTPase) through the use of a radioimmunoassay (RIA). A good description of RIA may be found in *Laboratory Techniques and Biochemistry in Molecular Biology*, by Work, T.S. *et al.*, North Holland Publishing Company, NY (1978) with particular reference to the chapter entitled "An Introduction to Radioimmune Assay and Related Techniques" by Chard, T., incorporated by reference herein. The radioactive isotope can be detected by such means as the use of a g counter or a scintillation counter or by autoradiography.

It is also possible to label an antibody in accordance with the present invention with a fluorescent compound. When the fluorescently labeled antibody is exposed to light of the proper wavelength, its presence can be then detected due to fluorescence. Among the most commonly used fluorescent labeling compounds are fluorescein isothiocyanate, rhodamine, phycoerythrine, pycocyanin, allophycocyanin, o-phthaldehyde and fluorescamine.

1982-01-01 10:00:00

The antibody can also be detectably labeled using fluorescence emitting metals such as  $^{152}\text{E}$ , or others of the lanthanide series. These metals can be attached to the antibody using such metal chelating groups as diethylenetriamine pentaacetic acid (ETPA).

The antibody can also be detectably labeled by coupling it to a chemiluminescent compound. The presence of the chemiluminescent-tagged antibody is then determined by detecting the presence of luminescence that arises during the course of a chemical reaction. Examples of particularly useful chemiluminescent labeling compounds are luminol, isoluminol, theromatic acridinium ester, imidazole, acridinium salt and oxalate ester.

Likewise, a bioluminescent compound may be used to label the antibody of the present invention. Bioluminescence is a type of chemiluminescence found in biological systems in which a catalytic protein increases the efficiency of the chemiluminescent reaction. The presence of a bioluminescent protein is determined by detecting the presence of luminescence. Important bioluminescent compounds for purposes of labeling are luciferin, luciferase and aequorin.

An antibody molecule of the present invention may be adapted for utilization in an immunometric assay, also known as a "two-site" or "sandwich" assay. In a typical immunometric assay, a quantity of unlabeled antibody (or fragment of antibody) is bound to a solid support or carrier and a quantity of detectably labeled soluble antibody is added to permit detection and/or quantitation of the ternary complex formed

between solid-phase antibody, antigen, and labeled antibody.

Typical, and preferred, immunometric assays include "forward" assays in which the antibody bound to the solid phase is first contacted with the sample being tested to extract the antigen from the sample by formation of a binary solid phase antibody-antigen complex. After a suitable incubation period, the solid support or carrier is washed to remove the residue of the fluid sample, including unreacted antigen, if any, and then contacted with the solution containing an unknown quantity of labeled antibody (which functions as a "reporter molecule"). After a second incubation period to permit the labeled antibody to complex with the antigen bound to the solid support or carrier through the unlabeled antibody, the solid support or carrier is washed a second time to remove the unreacted labeled antibody.

In another type of "sandwich" assay, which may also be useful with the antigens of the present invention, the so-called "simultaneous" and "reverse" assays are used. A simultaneous assay involves a single incubation step as the antibody bound to the solid support or carrier and labeled antibody are both added to the sample being tested at the same time. After the incubation is completed, the solid support or carrier is washed to remove the residue of fluid sample and uncomplexed labeled antibody. The presence of labeled antibody associated with the solid support or carrier is then determined as it would be in a conventional "forward" sandwich assay.

In the "reverse" assay, stepwise addition first of a solution of labeled

antibody to the fluid sample followed by the addition of unlabeled antibody bound to a solid support or carrier after a suitable incubation period is utilized. After a second incubation, the solid phase is washed in conventional fashion to free it of the residue of the sample being tested and the solution of unreacted labeled antibody. The determination of labeled antibody associated with a solid support or carrier is then determined as in the "simultaneous" and "forward" assays.

The present invention provides an immunoassay for the detection and quantification of a peptide of the invention. The creation of immunoassays, such as RIA or ELISA, has been described in many articles, textbooks, and other publications. Reference is made to WO 97/03998, p. 48, line 4 to p. 52, line 27. Immunoassays of the invention may be of two general types: Firstly, immunoassays using an immobilized peptide of the invention, may be used. Secondly, immunoassays using immobilized antibodies directed against an epitope of a peptide of the invention may be used to quantify a peptide of the invention.

In a preferred embodiment of the invention, the assay is an immunoblot assay. The sample, e.g., a cerebrospinal fluid (CSF) sample, is diluted, e.g., 1:10, in order to avoid overloading. The sample is then loaded onto a polyacrylamide gel, optionally a gradient gel, and electrophoresed. Synthetic or recombinantly produced peptide preferably SEQ. ID. No. 1, SEQ ID No. 2, or SEQ ID No. 3, may be added in separate lanes or spiked to the sample lanes, as positive controls. The gel is then blotted, preferably onto a Nitrocellulose or Nylon membrane. The blot is reacted with

antibodies against the acetylcholine-derived peptide, preferably antibodies reactive with SEQ. ID No. 1, 2 or 3. A more preferred antibody is the rabbit anti-GST-ARP antibody as described herein. Bound antibody may then be detected by antibodies reactive with the antibody of the invention, e.g., anti-rabbit immunoglobulins. These immunoglobulins are preferably labeled, e.g., by Peroxidase conjugation. The detection of the label is then carried out according to methods known in the art. Preferably, peroxidase-conjugated immunoglobulins are detected using the ECL™ detection system (Amersham Pharmacia Biotech, UK).

As described above, a preferred sample is serum. However, other body fluids may be used, including cerebrospinal fluid, liquor, saliva, and the like. Also, liquid extracts of body tissue may be analyzed. Alternatively, body tissue may be analyzed without extraction using cytochemical staining or immunostaining as described herein.

A preferred body fluid is cerebrospinal fluid. For instance, increased levels of AChE or of a peptide of the invention in cerebrospinal fluid, may be indicative of elevated blood cortisol levels, and may further be indicative of stress.

Such assays as hereinabove described may find use in diagnostics, as the level of the peptide of the invention may need to be evaluated in a number of conditions. For instance, such assays may be useful in order to monitor the effect of treatment of a patient with a peptide of the invention. Furthermore, such assays may be used in determining stress due to

psychological, chemical, or physical insult to the CNS (see Examples hereinbelow).

Thus, in a preferred embodiment, the invention provides a method for the diagnosis of psychological, chemical, or physical insult to the CNS, comprising obtaining a sample from said mammal, contacting said sample with an antibody of the invention, removing unbound antibody, and detecting the extent of reaction between said antibody and acetylcholinesterase or a fragment thereof present in said sample. The sample is preferably cerebrospinal fluid.

### Experimental Procedures

In situ hybridization: *In situ* hybridization procedures, were performed on cultured cells and tissues, as detailed elsewhere (Grisaru *et al.*, Mol. Cell. Biol. 19, 788-95, 1999, Kaufer *et al.*, Nature 393, 373-7, 1998). Cultured cells were centrifuged at 300 X g and fixed, using 4% paraformaldehyde, to collagen-coated cover slips placed on the bottom of the culture well. 5'-Biotinylated, 2'-O-methylated AChEcRNA probes complementary to 3'-alternative human *ACHE* exons were employed. Detection and quantification of the various AChEmRNA transcripts in fetal tissues were performed as previously described (Grisaru *et al.*, Mol. Cell. Biol. 19, 788-95, 1999). Confocal microscopy scans of the culture-derived cells were obtained using a MRC-1024 Bio-Rad confocal microscope (Hemel Hempstead Herts., UK). A projection was built from each cell image and specific criteria were set for size and intensity of the

Fast Red fluorescence. Image-Pro 3.0 software (Media Cybernetics, Silver Spring, MD, USA) was used to analyze the signals obtained. ANOVA (Analysis of Variance) test was used for calculation of p values.

Immunoblot: Mouse serum was diluted 1:10. ARP, ASP, recombinant AChE-S (Sigma Chemical Co.) and recombinant AChE-R extracted from transfected COS cells (Ben Aziz-Aloya *et al.*, Proc. Natl. Acad. Sci. USA 90, 2471-5, 1993, Seidman *et al.*, Mol. Cell. Biol. 15, 2993-3002, 1995) served as positive controls. Protein electrophoresis in SDS gradient (4-20%) polyacrylamide gels (Bio-Rad Laboratories, Hercules, CA) was followed by immunodetection using the rabbit anti-GST-ARP antibodies, Peroxidase-conjugated anti-rabbit immunoglobulins and ECL™ detection (Amersham Pharmacia Biotech, UK).

*Animal models and in vivo experiments* - transgenic FVB/N mouse pedigrees expressing human AChE variants were described elsewhere, as were the biochemical methods for measuring AChE activity (Sternfeld *et al.*, J. Physiol., Paris, 92, 249-55, 1998). The confined swim protocol for exerting acute psychological stress was performed as detailed (Kaufer *et al.*, Nature 393, 373-7, 1998). Immediately following the stress, the treated mice were injected intraperitoneally with 0.03 ng AS1 per gram body weight. Another group of non-stressed mice were injected with normal saline. Twenty-four hours later, the animals were sacrificed and peripheral blood was collected in EDTA covered tubes (Becton Dickinson Immunocytometry System, Inc., San Jose, CA) prepared with 25 units

of heparin sodium USP (Kamada LTD, Kibbutz Beit-Kama, Israel). Whole blood AChE activity was analyzed, and WBC and platelet counts determined, using an Ac-T diff hematology analyzer (Beckman Coulter, Inc., Fullerton, CA).

### Example 1

*Expression of recombinant ARP* - The sequence, coding the C-terminal region of I4 (i.e., the "readthrough" variant of acetylcholinesterase, comprising the ARP peptide sequence), was amplified by PCR using the following oligonucleotide primers:

GCT GGA TCC ATC GAG GGG CGA GGT ATG CAG GGG CCA GCG GGC (I4-up), also denoted as SEQ ID No. 4,

and TAT AAG CTT CTA GGG GGA GAA GAG AGG GGT (I4-down), also denoted as SEQ ID No. 5, and introduced into pGEX-KG (ATCC accession No. ATCC77103, see also Anal. Biochem. 192:262-267, 1991) plasmid.

*Antibody production* - GST and I4-GST fusion protein were purified from the supernatant of E. coli lysate by affinity chromatography on glutathione-Sepharose (Pharmacia), eluted with 10 mM reduced glutathione in 50 mM Tris-HCl, pH 8.0, dialyzed to 0.1 M ammonium acetate buffer, pH 7.0, aliquoted and lyophilized. The stability and identity of the protein was confirmed by SDS-PAGE. The following protease inhibitors were used during the preparation: aprotinin (10 microgram/ml), benzamidine (5 mM), Pefabloc SC (0.2 mM), and EDTA (1 mM). Prior to affinity chromatography, the E. coli lysate was incubated for 20 min at

37°C with 0.2 mM Mg-ATP in order to dissociate the fusion proteins from contamination of bacterial proteins. The procedure was performed according to Pharmacia recommendations.

Two New Zealand female rabbits were immunized subcutaneously with 0.3 mg fusion protein in complete Freund's adjuvant, and then reimmunized monthly with 0.2 mg fusion protein in incomplete Freund's adjuvant. Blood samples were taken 10 days after the immunization. The specific antibodies in the sera were detected by ELISA on immobilized fusion protein, in the presence of excess of soluble GST (20 microgram/ml). The reacting sera were chosen for antibody purification. The immobilized I4-GST, GST and *E. coli* lysate were prepared using Affigel 10 (Bio-Rad) according to the manufacturer's recommendations.

Crude IgG fraction was prepared from the serum by 50% saturation  $(\text{NH}_4)_2\text{SO}_4$  precipitation and dialyzed in 100 mM Tris-HCl, pH 8.0. In order to get rid of anti-GST antibodies, the IgG fraction was incubated with GST beads (Affigel 10, Bio-Rad) overnight at 4°C. The bound material was eluted with 4.5 M  $\text{MgCl}_2$ . The procedure was repeated with the unbound material several times, until no antibodies were eluted from GST beads. In order to get rid of antibodies against possible contamination of bacterial proteins, the same procedure was performed with immobilized heat-shocked *E. coli* lysate proteins.

The unbound material was then applied to I4-GST beads (Affigel 10, Bio-Rad), incubated 2 hr at room temperature or overnight at 4°C, and the bound material was eluted with 3.5 M  $\text{MgCl}_2$ . The eluted antibodies were

dialyzed against 10 mM Tris-HCl, pH 8.0, and then against PBS, containing 0.025% NaN<sub>3</sub>.

### Example 2

The inventors have found that ARP and AChE-R are regulated following psychological, chemical, or physical insult to the CNS, at both the mRNA and enzyme levels. Examples of chemical insult include exposure to harmful substances such as nerve gas or insecticide. Examples of physical insult include head injury, head trauma, irradiation insult, and the like.

Using high-resolution in-situ hybridization (performed essentially as described in Experimental Procedures) to paraffin embedded human tumor sections, the inventors have found intensive overexpression of AChE-R mRNA transcript in glioblastoma multiforme tumors and particularly in their highly proliferative margins, as compared to the benign brain tissue surrounding these surgically removed tumors. Moreover, AChE-R expression levels increased considerably in post-surgery brain sections, especially following irradiation. Pathologically-classified tumor specimens further revealed pronounced increases in the extent and incidence of glioblastoma AChE overproduction as related to tumor grading. These findings add to the general understanding of the molecular biology of glioblastoma tumors and can lead to novel, less harmful treatment paradigms.

The present inventors have also found, by in-situ hybridization as described hereinabove, that AChE-R mRNA changes its subcellular localization under stress. While under control conditions, said mRNA is detected exclusively in the soma of cortical neurons, following stress treatments AChE-R mRNA extends into the proximal domain of dendrites.

AChE expression was investigated in transgenic FVB/N mouse pedigrees expressing human AChE splice variants. As controls, extracts of *Xenopus laevis* oocytes expressing various human AChE splice variants, were used. The transgenic mouse lines and *Xenopus* expression systems are described in Sternfeld *et al.*, *J. Physiol.*, Paris, 92, 249-55, 1998, which publication is incorporated herein in its entirety by reference. The influence of stress was investigated using the confined swim protocol for exerting acute psychological stress as detailed by Kaufer *et al.*, *Nature* 393, 373-7, 1998.

Rabbit polyclonal antibodies against ARP (SEQ ID No 1) were obtained as described hereinabove. Antibodies against AChE common domain were obtained from a commercial supplier.

Extracts of *Xenopus* oocytes or of mouse brain tissue (cortex or basal nuclei), or human cerebrospinal fluid (CSF), were subjected to SDS-PAGE. Fig. 1 shows immunoblots of cerebrospinal fluid (CSF), recombinant AChE-S (rE6, Sigma), or AChE-R (I4 extracts, produced in *Xenopus* oocytes as detailed hereinabove). The antibodies directed against the C-terminal peptide of AChE-R, ARP (anti-I4, Fig. 1, right-hand side) fail to react with the AChE-S protein, because the intron 4 region is spliced out in

this mRNA. On the other hand, the antibodies clearly identify the AChE-R protein. Antibodies raised against the common domain of AChE (Fig. 1, left-hand side) are able to identify both AChE-R and AChE-S proteins.

In the following, "Non-stressed humans" refers to patients in which no enhanced Omnipaque signal was detected by CT brain scan, while "stressed humans" refers to patients in which an enhanced Omnipaque signal was detected by CT brain scan (see section hereinbelow relating to CT scans for details).

In cerebrospinal fluid of non-stressed humans (Fig. 1, "-"), no AChE can be detected by either antibody. In contrast, both antibodies readily detect AChE protein in the CSF of stressed human CSF (Fig. 1, "+"). The antibody against the common domain also detects a smaller fragment of AChE (Fig. 1, left-hand side). This fragment corresponds in size to a C-terminally truncated AChE-R protein. Indeed the antibody against the C-terminal peptide fails to detect this band (Fig. 1, left-hand side).

These experiments show that AChE occurs in increased levels in CSF upon CNS stress. The experiments also indicate that C-terminal truncation of AChE takes place. This may be due to increased proteolytic activity due to stress.

AChE could also be detected in mouse brain tissue. Fig. 2 shows extracts from the cortex and basal nuclei region obtained from the brain of control and human AChE transgenic mice. Transgenic FVB/N mouse pedigrees used herein, expressing human AChE variants, were described by Sternfeld *et al.*, J. Physiol., Paris, 92, 249-55, 1998. E6 in Fig. 2 denotes

a transgenic mouse expressing human AChE-S, In is a transgenic mouse expressing insertion-inactivated human AChE-S, I445 and I470A denote transgenic mice expressing various AChE-R constructs. The tissues were extracted, run on SDS-PAGE gels and blotted as described in the above Sternfeld *et al.* As a control, extracts from *Xenopus* oocytes expressing human AChE (E6), AChE-R (I4), or AChE-E (E4) were run in parallel. Fig. 2A shows detection of human AChE isoforms in transgenic mouse brain tissues by the antibody against the common domain of AChE. AChE is detected in cortex and basal nuclei. The transgenic mice expressing the insertion-inactivated AChE-S construct (In), show weak expression of AChE in basal nuclei, and fail to express AChE over the level of control (non-transgenic) mice in cortex (Fig. 2A).

The C-terminally truncated fragment of AChE was detected by these antibodies in all transgenic mice. The antibodies also detected a faint band corresponding in size to the C-terminally truncated AChE fragment, which is probably due to cross-reactivity.

When using the anti-ARP antibodies, similar results were obtained, with the exception that no smaller fragments could be detected (Fig. 2B).

### Example 3

#### *in-vivo* ARP effects

*ARP accumulates in the serum under stress* - To find out whether the ARP peptide occurs naturally in blood and if its levels increase under psychological stress, FVB/N mice (n=12) were subjected to confined swim

protocol for exerting acute psychological stress as detailed elsewhere (Kaufer *et al.*, Nature 393, 373-7, 1998). Serum samples removed 24 hr later were subjected to gradient gel electrophoresis. Fig. 3, top, shows a Ponceau-stained polyacrylamide gradient gel (4-20%, Bio-Rad) loaded with: (1) protein extract from COS cells transfected with AChE-R encoding plasmid (Ben Aziz-Aloya *et al.*, Proc. Natl. Acad. Sci. USA 90, 2471-5, 1993, Seidman *et al.*, Mol. Cell. Biol. 15, 2993-3002, 1995) and mixed with synthetic ARP (ARP+AChE-R); (2) recombinant AChE-S (Sigma), mixed with synthetic ASP (ASP+AChE-S); (3) serum (2  $\mu$ L) from a saline-injected mouse, removed 24 hr post-treatment (Control); (4) serum from a mouse subjected to confined-swim stress as described above, removed 24 hr post-treatment (Stress). Positions of molecular weight markers are shown on the left. The gel was then electroblotted and immunodetected (see "immunoblot" in the Experimental Procedures section for details) with affinity-purified rabbit antibodies elicited toward a recombinant GST-ARP fusion protein (Fig. 3, bottom). A 67 KDa protein, consistent with the expected size of AChE-R, is detected in the serum (upper arrow). Furthermore, selective labeling of synthetic ARP (but not AChE-S or ASP) by this antibody is detected. Accumulation of ARP in the serum of stressed mice is evident from the intense labeling of native ARP in the stressed mouse serum (lower arrow).

*ARP accumulation in the serum under stress.* The intense labeling of ARP in the unfractionated mouse serum removed 24 hr following stress treatment revealed more pronounced increases in this peptide than in its

native protein AChE-R. This may reflect elevated proteolytic activity under stress. Combined with the absence of cleavage sites for common proteases within the ARP sequence, this further explains the reproducible series of proteolytic degradation products of serum AChE-R which were intensified in the stressed serum samples. The physiological implications of this finding are that AChE catalytic activity measurements are underestimates of the extent of its overproduction in the blood under stress. Likewise, measuring acetylcholine hydrolysis may underestimate the actual amounts of the AChE protein and its degradation products in the brain or muscle. The reported decreases of AChE activity in Alzheimer's disease may hence mislead researchers and clinicians alike by masking the accumulation of morphologically active AChE-derived peptides with long-term effects.

### Example 3

#### **Disruption of the blood-brain barrier is associated with stress response**

In a search for the molecular parameters associated with Blood-Brain-Barrier (BBB) disruption, a quantitative approach for analyzing human brain images derived by Computerized Tomography (CT), Magnetic Resonance Imaging (MRI), or Single Photon Emission CT (SPECT) was developed. Fig. 4 B shows Computerized Tomography scans of patients with and without administration of Omnipaque (Nycomed AS), a soluble Iodine containing contrast agent. The figure demonstrates that in normal patients, little contrast agent penetrates into the brain.

However, in patients suffering from Eclampsia during pregnancy, or in patients suffering focal epileptic seizures, a significantly enhanced penetrance of Omnipaque into the brain was found (see arrow in Fig. 4B). In 17 out of 34 patients with diverse CNS related symptoms, greater than 50% increase in brain penetrance of the corresponding contrast agents, Omnipaque, gadolinium, or DTPA was observed. Fig. 5 A shows an example of enhanced Omnipaque signal revealed by CT scan versus control patients, also in post-ischemia patients.

When analyzing the above described data for the region of the brain showing greatest signal enhancement, significant signal enhancement was found in the Corona Radiata, Gray matter, and soft tissue regions. Very little enhancement of penetration of contrast agent into the Thalamus region was found, and the Cerebellum and Pons regions appeared unaffected. The percent enhancement of contrast agent signal was greatest (30% average) in the soft tissue (Fig. 5B).

These data indicate disruption of the BBB in patients with CNS pathologies. The data further show that disruption of CNS is associated with stress, and that the greatest extent of disruption of the BBB appears to occur in soft tissue, gray matter, and Corona Radiata regions.

In order to find out whether such disruption was linked to CNS stress, the signal enhancement (i.e., the percent increased penetrance of Omnipaque into the brain, as revealed by CT scan) was correlated to various stress parameters. Fig. 4 C shows that disruption of the BBB was indeed correlated with stress indicators such as heart rate, leukocyte

number, and serum cortisol levels. Blood pressure and body temperature, on the other hand, appeared not correlated to increased penetrance of contrast agents such as Omnipaque.

CSF samples taken from patients were run on SDS-PAGE gels, blotted, and stained with anti-AChE antibodies. The immunoblots revealed enhanced levels of AChE-R in samples of stressed patients.

The above results were confirmed in animal experiments. Mice subjected to confined swim stress protocol as described above were injected with Evans Blue, a dye that usually does not penetrate the BBB because of its association with blood albumin. Fig. 4A shows that a large amount of the dye penetrates the brain of stressed mice, as compared to very low levels in nonstressed control mice.

Claims

1. An antibody recognizing acetylcholinesterase or a C-terminal peptide derived from acetylcholinesterase, for use in diagnosing central nervous system (CNS) stress, elevated glucocorticoid level, or disruption of the blood-brain barrier.
2. The antibody of claim 1, wherein the CNS stress is caused by psychological, chemical, or physical insult.
3. The antibody of claim 2, wherein the CNS stress is caused by psychological insult.
4. The antibody of claim 1 which recognizes a C-terminal peptide derived from Acetylcholinesterase.
5. The antibody of claim 4, wherein the C-terminal peptide is SEQ ID no. 1, 2, or 3.
6. The antibody of claims 1 or 5 which is monoclonal.
7. A method for the diagnosis of central nervous system (CNS) stress, elevated glucocorticoid level, or disruption of the blood-brain barrier in a mammal, comprising obtaining a sample from said mammal, contacting said sample with an antibody of any one of claims 1 to 5, removing unbound antibody, and detecting the extent of reaction between said antibody and acetylcholinesterase or a fragment thereof present in said sample.
8. The method of claim 7 wherein the CNS stress is caused by physical, chemical, or psychological insult.

9. The method of claim 8 wherein the physical insult is head injury, head trauma, or exposure to irradiation.
10. The method of claim 8 wherein the chemical insult is exposure to insecticide or nerve gas.
11. A method of any one of claims 5 to 10 wherein the sample is a serum or cerebrospinal fluid sample.
